

Virginia Soybean Performance Tests 2022

Authored by David Holshouser, Professor and Extension Soybean Agronomist, Billy Taylor, Research Specialist, and Ronald Daughtrey, Ag Technician, Tidewater Agriculture Research and Extension Center.

Introduction

The purpose of this publication is to provide performance data of the many soybean varieties offered for sale in Virginia. These data should be of benefit to producers and agribusinesses in making selections of varieties for their use. It is realized that not all varieties that are offered for sale in Virginia are included in these tests. There is no implication that varieties not included are inferior in any way, but only that they have not been tested.

Virginia experienced variable weather between sites in 2022. Full-season yields were good, and in some cases very good. Orange (Northern Piedmont) and Suffolk (Southern Coastal Plain) received adequate rain all season and yields were good for all maturities. Similarly, yields were good at Warsaw (Northern Coastal Plain), but the environment favored later-maturing varieties. Dry weather persisted at Blackstone (Southern Piedmont) most of the year, but early August rainfall along with good management brought those yields to very respectable levels. Still, dry conditions during late-August through September resulted in smaller seed and lower yield, especially for the later-maturing varieties. The crop suffered on the Eastern Shore due to dry conditions much of the season; a heavy cover crop contributed to that by pulling out soil moisture early in the spring. Later rains, which favored maturity group 5 varieties, brought some relief, but yields were still low. Shattering (pre-harvest and during combining) was greater than in the past and may have affected the final yields at several sites. We did take pre-harvest shattering ratings in Blackstone and there were a few differences between varieties.

Only at Orange and Suffolk were double-crop yields equal or greater than average. Soybean was planted late at Blackstone and Warsaw due to dry soils (we waited on a rain to insure emergence). At Blackstone, final stands were poor (many plants died after emergence) and the remaining soybean never

grew over 9-12 inches in height; therefore, that site was not harvested.

Materials & Methods

Soybean varieties were entered by commercial seed companies, universities, crop improvement associations, and Virginia soybean farmers. Performance tests were conducted under full-season (May-planted) and/or double-crop (planted June to early-July) systems in the Northern Piedmont (Orange), Southern Piedmont (Blackstone), Northern Coastal Plain (Warsaw), Southern Coastal Plain (Suffolk), and Eastern Shore (Painter) regions of Virginia. All tests were no-till planted with an Almaco Seed Pro 6-row planter, except Warsaw that was planted in 30-inch rows. Recommended cultural practices were used and data were collected from a uniform set of instructions. Details of cultural practices used and soil types are listed on Tables on pages 3 and 4. Fertilizer was applied according to Virginia Tech soil test recommendations. Seed treatments were used on most seed, the chemical composition varying with company. Seeding rates were the equivalent to 140,000 seed per acre in full-season tests and 220,000 seed per acre in double-crop tests. All tests were maintained weed free with preemergence and/or postemergence herbicides and hand weeding. Insecticides were applied if insect pests approached economic thresholds. Fungicides were applied if disease was present and conditions were favorable for further disease progress. Tests were harvested as

near to the date of first harvest maturity as work schedules and weather would permit. Plots were end-trimmed to prevent alley effects. The interior four rows of all plots were harvested with a Wintersteiger Delta small-plot combine equipped with weigh scales, moisture meter, and on-board computer at 4 of 5 sites. At Warsaw, the middle 2 rows were harvested with a Zurn 150. A small seed sample was collected from each plot to evaluate seed characteristics. Data were collected using the following methods:

Maturity was measured at the date when 95% of the pods turned brown (R8) at Suffolk and Warsaw.

Lodging was visually estimated using a 1 to 5 scale according to the following criteria:

1.0 = almost all plants erect

2.0 = either all plants leaning slightly, or a few plants down

3.0 = either all plants leaning moderately (45° angle), or 25 to 50% down

4.0 = either all plants leaning considerably or 50 to 80% down

5.0 = all plants down

Plant Height was determined at maturity (R8) by measuring and averaging 3 to 5 randomly chosen plants. Height was measured from the ground to the uppermost main-stem node of the plant at maturity.

Purple Seed Stain (PSS) is the percentage of seed from a 100-seed sample that are affected with that disease.

Seed Quality ratings may represent Phomopsis seed decay and other seed disease. The following scale was used: 1.0 = very good; 2.0 = good; 3.0 = fair; 4.0 = poor; 5.0 = very poor.

Seed Size was obtained from the weight of a 100-seed sample then converted to number of seeds per pound.

Yield was measured as pounds per plot, adjusted to 13% moisture, and then converted to bushels per acre. A bushel weight of 60 pounds was used to determine yield.

Experimental design was a randomized complete block design with three replications per site. Due to the number of entries, it was necessary to separate the varieties by maturity in all locations. To facilitate field operations and to allow for more accurate comparison, maturity group IV and V varieties were separated into early (RM 4.0-4.6; 5.0-5.4) and late (RM 4.7-4.9; 5.5-5.9) relative maturity tests. Data were subjected to analysis of variance and means were separated with Fisher's Protected LSD test ($p = 0.10$).

Interpreting the Results

Tables 1a-1i contain full-season or double-crop yield summaries with 2- and/or 3-year averages where data is available. Past analysis of test data indicated that variety selection should be made from multiple years and sites. More sites result in information that is more reliable and a better indicator of how a variety will perform in the future. Not all varieties are tested in full-season and double-crop systems. Therefore, one should not use averages across full-season and double-crop systems to compare varieties. Varieties in the summary tables are ranked by average yield or relative yield across sites in descending order. The remaining pages (Tables 2a – 10d) contain detailed yield and other performance data from each site. Varieties are again sorted by yield. Traits shown in these tables include lodging, height, purple seed stain, seed quality, seed size, and yield. Upon request, these tables in an Excel spreadsheet can be provided.

It is not statistically correct to compare varieties from different maturity groups. However, it is recommended that producers select two to three of the highest yielding varieties from each maturity group adapted to his region in order to spread out harvesting time and yield risks associated with timing of summer rainfall patterns. The average performance of a variety over multiple environments is more reliable than its performance in one test. Because of year-to-year variability in variety performance, data for varieties with less than six site-years are considered preliminary. After examining these results, the farmer may want to plant limited quantities of several new better performing varieties to observe how they perform on their farm and under his management conditions. Within maturity groups at each location, LSD (least significant difference) was calculated at the 10% probability level. The LSD is a statistical test to assist the reader in comparing the yield differences among varieties within a particular maturity group. When two entries are compared and the difference between them is greater than the calculated LSD value, the varieties are considered significantly different. The coefficient of variation (CV) is a relative measure of variation and is an indicator of the degree of precision associated with the test. CV values less than 15% indicates that the precision of the test was good in distinguishing differences between varieties.
